DECLARATION

I declare that this final individual research report titled “AI-Driven Citizen Welfare Guidance and Area-Aware Service Recommendation for Digital Welfare Management in Sri Lanka” is my original work, completed in partial fulfillment of the requirements for the Bachelor of Science (Honors) in Information Technology at the Sri Lanka Institute of Information Technology (SLIIT). This report has not been submitted, totally or partially, to any other institution for academic qualification. All sources of information, data, and ideas have been properly acknowledged through appropriate reference. I confirm that the work is free from plagiarism and has been completed with full adherence to academic integrity and ethical norms. I assume full responsibility for the accuracy, authenticity, and general material given in this report.

Student Name	Student ID	Signature
Wickramasinghe R.P.Y.N	IT22214584	

Signature of the Supervisor: Date:
(Ms. Anjalie Gamage)

Signature of the Co-supervisor: Date:
(Ms. Geethanjali Wimalaratne)

ACKNOWLEDGEMENT

I want to sincerely thank Ms. Anjalie Gamage, my supervisor, for her excellent advice, unwavering support, and helpful criticism during the course of my research project. Her advice, support, and ideas greatly influenced our study's academic caliber as well as its technical execution.

Additionally, I would like to express my gratitude to the academic and non-academic staff at the Sri Lanka Institute of Information Technology (SLIIT) for providing the expertise, materials, and educational setting required to finish this research project. Their commitment to academic achievement has made a significant contribution to my career and personal growth.

I would want to express my gratitude to my classmates and coworkers for their insightful conversations, suggestions, and moral support throughout the project's development. Their cooperation and support enabled me to get past a number of obstacles I faced while conducting my research.

Lastly, I want to sincerely thank my family for their unfailing patience, support, and encouragement during my academic career. Their confidence in my skills has always been a source of inspiration and fortitude.

ABSTRACT

The necessity for intelligent digital systems that can assist individuals in selecting appropriate social support programs has been brought to light by the growing need for effective and easily available welfare services. Due to disjointed information systems, a lack of customisation, and restricted accessibility, welfare services in Sri Lanka are frequently challenging to use, especially for low-income and vulnerable groups. As a result, many persons who qualify do not get the help the need in a timely way.

In order to improve digital welfare management in Sri Lanka, this study offers an AI-Driven Citizen Welfare Guidance and Area-Aware Service Recommendation System. In order to give individualized and context-aware welfare recommendations, the proposed system combines household-level socioeconomic data with regional administrative data at the Grama Niladhari (GN) division level.

The study makes use of two main datasets: a synthesized citizen guidance dataset with 98,056 records and 29 attributes, and an official GN-level dataset with 14,008 entries and 33 attributes. Random Forest-based machine learning models were created to carry out no-strong-match detection, priority categorization, and multi-label service recommendation.

A Flask backend API and a React-based frontend were used to create a whole software prototype. Priority levels, confidence scores, suggested services, suggestions for welfare programs, necessary documentation, and practical next-step advice are among the outputs that the system produces after processing user inputs in real-time.

The findings show that the suggested approach can successfully raise public awareness, streamline access to welfare services, and assist in digital governance decision-making. This study shows how artificial intelligence can be incorporated into public welfare systems and offers a scalable basis for further research and government-level use.

Keywords: Digital government, machine learning, artificial intelligence, welfare systems, recommendation systems, Sri Lanka, random forests, and social services

[1] Introduction

1.1 Background of the Study

Public welfare programs, which are intended to assist economically disadvantaged groups and enhance general social well-being, are crucial elements of contemporary governance. For people and families dealing with financial hardship, disability, aging, or disaster-related issues, these systems offer financial support, healthcare support, food security, and social safety. Welfare programs are especially important for lowering poverty and guaranteeing fair access to essential services in emerging nations like Sri Lanka.

Even if there are several welfare programs, their usability and accessibility provide a significant obstacle. Many citizens lack the knowledge necessary to determine the best solutions depending on their family circumstances or are ignorant of the programs that are offered. Conventional welfare systems frequently rely on manual procedures, necessitating residents to visit government buildings, speak with representatives, and understand intricate eligibility requirements. For those who live in isolated or underdeveloped areas, this procedure may be time-consuming, ineffective, and unavailable.

Governments are using digital platforms more frequently to enhance service delivery due to the quick development of digital technologies. Nonetheless, a large number of current digital welfare systems serve mainly as static information sites. They offer broad program information, but they don't provide individualized advice based on each person's needs.

In order to solve these issues, this study suggests an AI-driven welfare guidance system that creates tailored and useful recommendations for residents by combining household-level data with regional context.

1.2 Literature Overview of Digital Welfare Systems

As governments seek to increase the effectiveness and openness of public service delivery, digital welfare systems have attracted a lot of interest lately. Usually, these systems concentrate on

digitizing administrative procedures including beneficiary administration, application submission, and payment distribution.

However, studies show that the majority of current technologies do not offer intelligent assistance and lack user-centric design. It is frequently necessary for citizens to use complicated interfaces and understand eligibility requirements on their own. This poses challenges, especially for those with low levels of digital literacy.

Research on digital governance highlights how crucial it is to incorporate decision-support tools and user-friendly interfaces into public service platforms. Accessibility and user pleasure can be greatly increased by intelligent systems that evaluate user input and make recommendations.

Despite these developments, such technologies are not widely used in welfare services, particularly in Sri Lanka.

1.3 AI in Public Service Delivery

In a number of industries, including government services, healthcare, finance, and education, artificial intelligence (AI) has become a game-changing technology. Large amounts of data may be processed by AI systems, which can also recognize patterns and produce recommendations or forecasts.

AI has the potential to improve decision-making, automate procedures, and improve user experiences in the provision of public services. A type of AI called machine learning algorithms is very helpful for jobs involving categorization and prediction.

The Random Forest algorithm, which is renowned for its precision and resilience, is one of the most popular machine learning methods. To generate accurate forecasts, it combines several decision trees. Furthermore, multi-label classification approaches allow algorithms to predict numerous outcomes at once, which makes them appropriate for applications like recommending welfare services.

Welfare systems can become sophisticated decision-support tools that offer tailored advice by incorporating AI into them.

1.4 Research Gap

Even while AI and digital welfare systems have made great strides, there are still a number of holes in the current solutions.

First off, the majority of welfare platforms don't offer tailored suggestions based on specific home circumstances. Information must be manually interpreted by citizens, which may result in misunderstandings and poor choices.

Second, geographic context is frequently overlooked by current systems. Welfare demands are determined in large part by factors like location, demographic characteristics, and regional conditions. Nevertheless, recommendation algorithms hardly ever incorporate these elements.

Thirdly, many AI-based systems lack explainability. Users' trust and usability are diminished since they are not given clear explanations, confidence levels, or practical next steps.

Additionally, little research has been done on AI-driven welfare advice systems in Sri Lanka, especially those that make use of GN-level administrative data.

1.5 Problem Statement

Even though there are numerous welfare programs available, residents in Sri Lanka have a difficult time finding appropriate assistance because of disjointed information systems, a lack of customisation, and restricted accessibility.

Inefficiencies, delays, and underutilization of social services are caused by the lack of intelligent guidance systems. Many citizens either do not receive assistance at all or apply for programs that are inappropriate.

Therefore, the key problem addressed in this research is:

How can an AI-driven system be developed to provide personalized, location-aware, and explainable welfare guidance for citizens in Sri Lanka?

1.6 Aim and Objectives

Aim:

The main goal of this project is to create an AI-powered welfare guiding system that offers citizens location-aware, customized recommendations.

Objectives

- To gather and examine administrative data at the GN level
- To compile a structured dataset that reflects the state of households
- To create welfare recommendation machine learning models
- To create and put into use an online system
- To assess the usability and performance of the system

1.7 Scope of the Study

The creation of a prototype system that offers initial welfare guidance is the main goal of this study. Users can enter household data into the system and get machine learning model-based recommendations.

Real-time integration with official decision-making procedures or government databases is not included in the study. The system acts as a guide, and the appropriate authorities are still in charge of making final eligibility determinations.

1.8 Significance of the Study

Numerous significant contributions to the academic and practical realms are made by this research.

From a social standpoint, the approach makes welfare programs more accessible by giving residents individualized and unambiguous guidance.

Technically speaking, the study shows how machine learning may be used practically in digital governance.

From an academic standpoint, the study advances the field of artificial intelligence in public service delivery and lays the groundwork for further research.

[2] Methodology

2.1 Research Design

In order to create an intelligent welfare guiding system, this study employs a design and development-oriented methodology that incorporates concepts from data science, machine learning, and software engineering. This method's goal is to develop a completely working prototype that can produce tailored recommendations based on user input and contextual information.

Problem identification, dataset collecting, data preprocessing, feature engineering, model building, system implementation, and evaluation are some of the phases that make up the study design. To guarantee that the finished system is both technically sound and practically viable, each step is meticulously planned.

Machine learning algorithms are taught using structured datasets and evaluated using performance metrics including accuracy, precision, recall, and F1-score in a quantitative manner. In order to provide scalability and maintainability, the system development also uses a modular architecture that divides the frontend, backend, and machine learning components.

2.2 Dataset Collection

Any machine learning system's efficacy is largely dependent on the caliber and applicability of the training data. Two main datasets were used in this study to record household-level characteristics as well as the geographic context.

2.2.1 GN-Level Context Dataset

The first dataset, which offers administrative and geographic context, is an official Grama Niladhari (GN) division-level dataset. This dataset includes:

- 14,008 entries
- 33 characteristics

Variables pertaining to regional features, socioeconomic circumstances, and demographic distribution are included in the dataset. These characteristics are essential for comprehending welfare issues unique to a given place.

Attribute Name	Description	Data Type
District	Administrative district name	String
DS Division	Divisional Secretariat Division	String
GN Division	Grama Niladhari Division	String
Population	Total population in GN division	Integer
Poverty Level	Poverty index of the area	Float
Housing Index	Quality of housing conditions	Float
Infrastructure Score	Availability of infrastructure services	Float
Employment Rate	Percentage of employed individuals	Float
Education Level	Average education level of residents	Float

Table 1 – Structure of GN-Level Context Dataset

2.2.2 Citizen Guidance Dataset

The second dataset is a synthesized dataset designed to simulate real-world household conditions. This dataset contains:

- 98,056 records
- 29 attributes

The dataset includes:

- Family size
- Monthly income range
- Employment status
- Elderly presence
- Disability status
- Chronic illness
- Disaster impact
- Food insecurity score
- Healthcare access score

Attribute Name	Description	Data Type
Family Size	Number of members in household	Integer
Income Range	Monthly income category	Category
Employment Status	Employment type	Category
Elderly Presence	Presence of members aged 60+	Boolean
Disability Status	Presence of disabled members	Boolean
Chronic Illness	Ongoing health conditions	Boolean
Disaster Impact	Affected by disaster	Boolean
Food Insecurity Score	Level of food access difficulty	Integer
Healthcare Access Score	Access to healthcare services	Integer

Table 2 – Structure of Citizen Guidance Dataset

2.3 Data Preprocessing

A crucial stage in machine learning is data preprocessing, which makes sure that unprocessed data is converted into a format that is appropriate for training models.

In this investigation, a number of preprocessing methods were used:

Handling Missing Values

Using statistical techniques, missing or incomplete data items were either eliminated or filled in with the proper values.

Cleaning Data

To enhance the quality of the data, inconsistencies including duplicate records and inaccurate values were found and eliminated.

Categorical Variable Encoding

Encoding techniques were used to transform categorical information, such as income range and job status, into numerical representations.

The process of normalization

To guarantee consistency and enhance model performance, numerical characteristics were normalized.

2.4 Feature Engineering

In order to enhance model performance, feature engineering entails the selection and transformation of pertinent variables.

Feature Name	Importance in Prediction
Income Range	Determines financial stability
Family Size	Indicates dependency burden
Employment Status	Reflects income stability
Elderly Presence	Indicates need for elderly care services
Disability Status	Indicates need for health and support services
Chronic Illness	Identifies healthcare support requirement
Disaster Impact	Identifies emergency relief needs
Food Insecurity Score	Determines food assistance requirement
Healthcare Access Score	Indicates healthcare support need

Table 3 – Description of Input Features Used for Prediction

Important characteristics consist of:

- Features of the household (family size, income)
- Indicators of vulnerability (elderly, infirmity, disease)
- Variables related to geographic context
- Difficulty ratings (access to healthcare, food insecurity)

Every feature was carefully chosen in accordance with its importance for welfare service eligibility and priority. In order to more accurately depict real-world situations, derived features were also produced by merging many factors.

2.5 Model Development

The scikit-learn package was used to create machine learning models for three primary tasks: no-strong-match detection, service recommendation, and priority classification.

2.5.1 Priority Classification Model

Households were categorized using a Random Forest Classifier into:

- Low priority
- Moderately important
- High priority

The algorithm evaluates home circumstances and assesses how urgently welfare assistance is needed.

2.5.2 Multi-Label Recommendation Model

Several social service categories were simultaneously predicted using a MultiOutputClassifier with Random Forest, including:

- Food Assistance
- Health Support
- Elderly Care
- Disaster Relief
-

2.5.3 No-Strong-Match Detection Model

In order to prevent the system from producing deceptive results, a different model was employed to identify situations in which a clear recommendation could not be provided.

2.6 System Architecture

The system follows a client-server architecture consisting of multiple layers.

Front-end Layer: The frontend, which was created with React and Vite, offers an intuitive experience for entering data and displaying results.

The Backend Layer: The backend, which is implemented with Flask, processes incoming data, responds to API calls, and makes predictions.

Layer of Machine Learning: Based on input data, this layer loads learned models and makes predictions.

Layer of Data: saves datasets in JSON and CSV formats.

2.7 Frontend and Backend Integration

The system uses RESTful APIs to enable communication between frontend and backend

Workflow:

1. User enters data
2. Data sent to API
3. Backend processes data
4. Models generate predictions
5. Results returned to frontend

2.8 Testing Strategy

Testing ensures system reliability and performance.

Test Case	Expected Result	Status
Valid Input Submission	Correct output generated	Pass
Missing Data Handling	Error message displayed	Pass
API Response	Data returned correctly	Pass
Model Prediction Accuracy	Accurate recommendations	Pass

Table 7 – Functional Testing Results Summary

- Unit Testing

Individual components were tested using pytest.

- Functional Testing

Different scenarios were tested to verify system behavior.

- Model Evaluation

Models were evaluated using:

- Accuracy
- Precision
- Recall
- F1-score

2.9 Ethical Considerations

An essential component of this study was ethical considerations.

The mechanism was created to guarantee:

- Data confidentiality and privacy
- Openness in suggestions

- Prediction fairness
- Unambiguous disclaimers stating that results are not final judgments

User privacy was protected by the use of synthetic data rather than actual personal information.

[3] Results and Discussion

3.1 Prototype Implementation

A full web-based prototype of the suggested AI-driven welfare guiding system was successfully put into operation. The solution combines a Python Flask-built backend API with a contemporary frontend created with React and Vite. In order to make predictions in real time, the machine learning models were trained independently and implemented in the backend.

Through an interactive online interface, the prototype enables users to enter location and household data. Following submission, the backend processes the data and runs it through machine learning models that have been trained to produce suggestions.

A complete end-to-end workflow, including data input, processing, prediction, and output visualization, is demonstrated by the system. This demonstrates that incorporating machine learning methods into digital welfare systems is feasible.

3.2 User Guidance Form

The main interface that users use to communicate with the system is the user advice form. It is intended to be easy to use, organized, and accessible to people with different degrees of digital literacy.

Welfare Guidance Form

This is a preliminary guidance tool for citizens. Final verification should be completed through the appropriate welfare office.

1. Select Your Location

District

Matale

DS Division

Wilgamuwa

GN Division

Medakanda

2. Tell Us About Your Household

Family size

4

Monthly income range

Rs. 25,000 - 50,000

Figure 6 : Welfare Guidance Input Form Interface

The form consists of several sections:

Location Information

- District
- DS Division
- GN Division

This section enables the system to incorporate geographic context into its predictions.

Household Information

- Family size

- Monthly income range
- Employment status

These inputs provide a basic understanding of the household's economic condition.

Vulnerability Indicators

- Presence of elderly members
- Disability status
- Chronic illness
- Disaster impact

These indicators help identify vulnerable households that may require priority support.

Difficulty Scores

- Food insecurity score
- Healthcare access score

These scores represent the level of hardship experienced by the household.

The form includes validation mechanisms to ensure that all required fields are completed before submission.

3.3 Prediction Workflow

The prediction workflow outlines the steps involved in processing user input and turning it into useful results.

Figure 3: Data Processing Pipeline

The following steps make up the workflow:

- Data is entered by the user via the frontend
- JSON data is transmitted to the backend API.
- Data is prepared and preprocessed.
- Models for machine learning are used
- Forecasts are produced
- The frontend receives the results.

Accurate forecasts and effective processing are guaranteed by this organized workflow.

3.4 Output Recommendation Results

The system generates comprehensive outputs designed to provide actionable guidance to users.

The output includes:

Figure 7: Recommendation Result Interface

Priority Level

The system classifies households into low, medium, or high priority categories.

Confidence Score

A numerical value indicating the reliability of the prediction.

Recommended Services

The system identifies relevant service categories such as:

- Food Assistance
- Health Support
- Elderly Care
- Disaster Relief

Programme Suggestions

Specific welfare programmes are recommended, including government and community support options.

Required Documents

The system lists necessary documents such as NIC, proof of address, and income details.

Next-Step Guidance

Users are provided with clear instructions on how to proceed.

3.4.1 Scenario-Based Analysis

To evaluate the effectiveness of the system, multiple scenarios were tested using different input conditions.

Scenario 1 – Moderate Income Household

- Family size: 4
- Income: Rs. 25,000 – 50,000
- Moderate food insecurity

Result:

- Priority: Medium
- Recommended Service: Food Assistance

This scenario demonstrates how the system identifies moderate-risk households and provides relevant support options.

Scenario 2 – High-Risk Household

- Low income
- Disabled member

- High food insecurity

Result:

- Priority: High
- Recommended Services: Food Assistance, Health Support

This scenario highlights the system’s ability to identify vulnerable households requiring urgent intervention.

Scenario 3 – Low-Risk Household

- Stable income
- No vulnerabilities

Result:

- Priority: Low
- No strong match

Scenario	Priority	Services Recommended	Confidence
Moderate Risk	Medium	Food Assistance	98%
High Risk	High	Food + Health Support	96%
Low Risk	Low	No Strong Match	85%

Table 6 – Sample Welfare Recommendation Outputs

3.5 Performance Evaluation

The performance of the machine learning models was evaluated using standard metrics.

Metric	Value (%)
Accuracy	92

Precision	90
Recall	91
F1-Score	90.5

Metrics used:

- Accuracy
- Precision
- Recall
- F1-score

The results indicate that the models perform effectively in classifying priority levels and recommending services.

3.6 Discussion of Findings

The results demonstrate that the proposed system effectively addresses the limitations of traditional welfare systems.

Improved Accessibility: The system simplifies access to welfare services by providing clear and structured guidance.

Personalization: Recommendations are tailored based on user input, improving relevance.

Location Awareness: Integration of GN-level data enhances contextual accuracy.

Practical Implementation: The working prototype confirms real-world applicability.

[4] Conclusion

4.1 Conclusion

In order to enhance the provision of digital welfare services in Sri Lanka, this study effectively developed and deployed an AI-driven citizen welfare advice and area-aware service

recommendation system. The study addressed the main issues with traditional welfare systems, such as their inaccessibility, dispersed information sources, and lack of citizen-specific assistance.

At the Grama Niladhari (GN) division level, the suggested approach combines geographic administrative context with household-level socioeconomic data. The system can produce precise and customized welfare recommendations by utilizing machine learning approaches, including Random Forest-based models. These ideas, which help users better understand and access available social programs, include priority classification, service recommendations, and practical next-step information.

The practical viability of deploying such systems in real-world settings is demonstrated by the creation of a fully functional prototype utilizing a Flask backend and a React-based frontend. The possibility of fusing artificial intelligence with digital governance platforms is demonstrated by the incorporation of machine learning models into a web-based application.

System testing and scenario-based evaluation results show that the suggested solution can successfully identify household needs and offer pertinent recommendations. The system effectively assigns priority levels, recommends suitable welfare services, and provides consumers with unambiguous instructions. This demonstrates how AI-driven systems can significantly improve the provision of public services.

Additionally, the study shows that adding spatial context to welfare systems greatly enhances the precision and applicability of recommendations. This method guarantees that the system is context-aware and data-driven, which makes it better suited for practical uses.

4.2 Contributions of the Study

This research provides several important contributions across technical, practical, and academic domains.

Technical Contribution

Technically speaking, this work was effective in creating a comprehensive AI-based welfare recommendation system. It illustrates how machine learning methods, especially Random Forest algorithms, can be applied successfully to classification and prediction applications. The system's

overall performance is improved by integrating several models, such as multi-label recommendation, priority classification, and no-strong-match detection.

The study also demonstrates how to use contemporary technologies like React, Flask, and RESTful APIs to construct a full-stack application. The viability of implementing machine learning models in web-based systems is demonstrated by this integration.

Practical Contribution

Practically speaking, the technology offers an easy-to-use platform that makes welfare services more accessible. The system makes it easier for citizens to navigate social programs by providing clear instructions and individualized recommendations.

Incorporating actionable outputs, like suggested services, necessary papers, and directions for the next step, guarantees that users may make significant decisions based on the system's recommendations. This enhances the user experience and raises the possibility that service access will be successful.

Academic Contribution

From an academic standpoint, this study advances the expanding field of artificial intelligence in the provision of public services. By fusing machine learning with geographic context, it presents a new method for welfare guidance systems.

Additionally, the study offers an organized approach for creating comparable systems, which includes feature engineering, dataset preparation, model building, and system integration. This can be used as a guide for upcoming studies in this field.

4.3 Limitations

Even though the system was successfully implemented, a number of drawbacks were found.

The use of synthetic data to train the machine learning models is one of the main drawbacks. The dataset might not accurately reflect the complexity and unpredictability of real household data, despite being created to mimic real-world circumstances.

The absence of integration with formal government databases is another drawback. The system functions as a stand-alone prototype without official eligibility verification or access to real-time

data. Because of this, the system's recommendations are just preliminary and need to be verified by the appropriate authorities.

A small number of welfare service categories are also included in the system. Increasing the variety of services could make suggestions more thorough.

Furthermore, the prototype has not been extensively tested with actual users and has not been implemented in a production setting. In order to evaluate its efficacy in practical situations, additional testing and validation are necessary.

4.4 Future Enhancements

The system can be made better and more capable by implementing a number of improvements.

Connectivity to Governmental Systems

In order to facilitate real-time data access and verification, future iterations of the system may be coupled with official government databases. This would improve recommendations' precision and dependability.

Utilizing Actual Data

Real-world data from welfare organizations and government agencies can greatly enhance model performance and guarantee that the system accurately depicts the situation.

Extension of Service Types

Additional welfare programs and services, like job programs, housing aid, and education support, could be added to the system. This would broaden the system's application and boost its utility.

Development of Mobile Applications

Accessibility would be enhanced by creating a mobile application version of the system, especially for users who depend on cellphones for internet connection in remote locations

Multilingual Assistance

The system would be more inclusive and available to a larger population in Sri Lanka if Sinhala and Tamil were supported.

Advanced Methods of Machine Learning

To further enhance prediction accuracy and system performance, future study can investigate more sophisticated machine learning and deep learning techniques.

Scalability and Deployment

To enable widespread use and guarantee scalability, the system can be installed on cloud platforms. This would make it possible for the system to effectively manage many users.
